**Logging Operation Notes:**

Logging was conducted with a centralizer on the sondes. Data were mostly acquired in a single casing. Exceptions include depth intervals below the bottom of each casing where the sonde entered an open hole. All measurements are referenced to ground surface.

**Analysis Notes:**

<b>Analyst:</b>	Henwood	<b>Date:</b>	08/13/08	<b>Reference:</b>	GJO-HGLP 1.6.3, Rev. 0
-----------------	---------	--------------	----------	-------------------	------------------------

Pre-run and post-run verifications for the logging systems were performed before and after each day's data acquisition. The acceptance criteria were met.

Three different sized casings were used in drilling this borehole. A casing correction for a 7/8-in.-thick casing was applied to the SGLS data (log run 1) to 108 ft.; no casing correction was applied at 109 ft. For log run 5, a casing correction for 5/8 in. thick casing was applied from 108 to 234 ft.; no correction was applied at 235 ft. For log run 10, a casing correction for 3/8-in. thick casing was applied from 233 to 267 ft.; no correction was applied at 268 ft. Data acquired below 259.7 ft. were corrected for water.

The moisture data are reported in counts per second (cps) as there is no valid calibration available for the casings used in this borehole. The data reflect relative moisture content.

SGLS spectra were processed in batch mode using APTEC SUPERVISOR to identify individual energy peaks and determine count rates. Concentrations were calculated with EXCEL worksheet templates identified as G4LDec07.xls and G1NMar08.xls using efficiency functions and corrections for casing, dead time, and water as determined from annual calibrations.

**Results and Interpretations:**

Cs-137 was detected near the ground surface (0 to 2 ft.) at a maximum concentration of approximately 1.5 pCi/g. Other detections in the borehole were determined to be the result of statistical fluctuations from the routine processing software and full energy peaks did not exist.

MDLs for processed uranium (U-238 and U-235) are plotted because uranium exists in the groundwater in the area and a vadose zone source for this contamination is being investigated. No uranium was detected in the vadose zone. Several detections from the routine processing software were determined to be invalid as no full energy peak existed in the spectra.

The neutron moisture data log indicates an abrupt increase in relative moisture content between 220 and 237 ft. The increased moisture content appears to occur between two silty layers, which are seen as increases in Th-232 concentration. Similar zones have been observed in boreholes 299-E33-18, -343, -344, and -345 that exist in the same geographical area.

Repeat sections acquired for each logging system indicate good repeatability.
